VAEs

Optimizing the ELBO:

$$\mathbb{E}_{Q_\phi} \left[\log P(x|z, \theta) \right] \quad \left. \vphantom{\mathbb{E}_{Q_\phi} \left[\log P(x|z, \theta) \right]} \right\} \text{Reconstruction loss.}$$
$$- \mathbb{E}_{Q_\phi} \left[\log \frac{Q(z|x, \phi)}{P(z|\theta)} \right] \quad \left. \vphantom{\mathbb{E}_{Q_\phi} \left[\log \frac{Q(z|x, \phi)}{P(z|\theta)} \right]} \right\} \text{KL divergence.}$$

Procedure to optimize the ELBO with the ANNs ϕ and θ . (see notes #9).

- Reconhass function:

- using the data X , pass them through the VAE to obtain the output X^*
- Make X^* as close as possible to X .
- \mathbb{E}_{Q_ϕ} means take the average when the $z \sim Q_\phi$

- KL Divergence:

- depends on the distributions for ϕ and θ .
- Example with two Gaussian distributions in "STA2536 - 08. pdf", e.g.

$$\mathbb{E}_{Q_\phi} \left[-\frac{1}{2} \left(d \cdot \log 2\pi + \log (\det \Sigma_\theta(z)) + (x - \mu_\theta(z))^T \Sigma_\theta^{-1}(z) (x - \mu_\theta(z)) \right) \right]$$
